Question 1

Let n be a positive integer that is not a perfect square. Prove that \sqrt{n} is irrational.

Solution: Assume, for contradiction, that \sqrt{n} is a rational. Then \sqrt{n} can be written in the form $\frac{a}{b}$ where $a, b \in \mathbb{Z}$ and a, b are coprime, or have no common factors.

We have

$$\frac{a}{b} = \sqrt{n} \implies \left(\frac{a}{b}\right)^2 = n \implies a^2 = nb^2 \quad (1)$$

This means that n divides a^2 . By the Fundamental Theorem of Arithmetic we can write a , n , and b as unique product of primes.

Thus,

$$a^2 = nb^2 \implies \left(\prod_{i=1}^k P_i^{n_i}\right)^2 = \prod_{j=1}^l P_j^{m_j} \left(\prod_{k=1}^t P_k^{l_k}\right)^2 \quad (2)$$

After simplification of (2) we have

$$\prod_{i=1}^k P_i^{2n_i} = \prod_{j=1}^l P_j^{m_j} \prod_{k=1}^t P_k^{2l_k} \quad (3)$$

In both expressions of a^2 and b^2 , as a product of primes, we have an even number of each prime in the product. Because n is not a perfect square, there must be at least 1 prime that is expressed an odd number of times. We are then guaranteed that by expressing nb^2 as a product of primes there must be at least 1 prime which appears an odd number of times. However, the left hand side of (3) clearly shows this is not the case \rightarrow .

With this contradiction we have no choice but to overturn our assumption and conclude that $\sqrt{n} \in \mathbb{R} \setminus \mathbb{Q}$ \odot

Question 2

Use the Principle of Mathematical Induction to prove:

$$1^2 + 3^2 + \dots + (2n-1)^2 = \frac{4n^3 - n}{3} \quad \forall n \in \mathbb{N}$$

Solution:

Let $n = 1 \in \mathbb{N}$. Then $1^2 = \frac{4(1)^3 - 1}{3} = 1$, showing that the equality holds for $n = 1$. We assume that

$$1^2 + 3^2 + \dots + (2n-1)^2 = \frac{4n^3 - n}{3},$$

is true and we proceed with induction on n . We want to show $P(n+1) = \frac{4(n+1)^3 - (n+1)}{3}$.

Consider

$$\begin{aligned} 1^2 + 3^2 + \dots + (2n-1)^2 + (2(n+1)-1)^2 &= \frac{4n^3 - n}{3} + (2(n+1)-1)^2 \\ &= \frac{4n^3 - n}{3} + (4n^2 + 4n + 1) \\ &= \frac{4n^3 - n + 12n^2 + 12n + 3}{3} \\ &= \frac{4n^3 + 8n^2 + 4n + 4n^2 + 8n + 4 - n - 1}{3} \\ &= \frac{4[n^3 + 2n^2 + n + n^2 + 2n + 1] - (n+1)}{3} \\ &= \frac{4[(n^2 + 2n + 1)(n+1)] - (n+1)}{3} \\ &= \frac{4(n+1)^3 - (n+1)}{3} \end{aligned}$$

$$= \frac{4(n+1)^3 - (n+1)}{3}.$$

Thus, $P(n+1) = \frac{4(n+1)^3 - (n+1)}{3}$, proving $1^2 + 3^2 + \dots + (2n-1)^2 = \frac{4n^3 - n}{3} \quad \forall n \in \mathbb{N} \quad \odot$

Question 3

Let $n > 1$ be a positive integer and let a_1, a_2, \dots, a_n be real numbers. Prove that

$$\left| \sum_{k=1}^n a_k \right| \leq \sum_{k=1}^n |a_k|$$

Solution: Let $n = 2 \in \mathbb{Z}^+$. Then

$$\left| \sum_{k=1}^2 a_k \right| \leq \sum_{k=1}^2 |a_k| \implies |a_1 + a_2| \leq |a_1| + |a_2|,$$

which we know is true by the Triangle Inequality Theorem. We then want to show that $\left| \sum_{k=1}^{n+1} a_k \right| \leq \sum_{k=1}^{n+1} |a_k|$. We assume for proof by induction that

$$\left| \sum_{k=1}^n a_k \right| \leq \sum_{k=1}^n |a_k|$$

is true. Expanding yields

$$|a_1 + a_2 + \dots + a_n| \leq |a_1| + |a_2| + \dots + |a_n|.$$

Adding $|a_{n+1}|$ to both sides results in

$$|a_1 + a_2 + \dots + a_n| + |a_{n+1}| \leq |a_1| + |a_2| + \dots + |a_n| + |a_{n+1}|,$$

and by the Triangle Inequality Theorem we have

$$|a_1 + a_2 + \dots + a_n + a_{n+1}| \leq |a_1 + a_2 + \dots + a_n| + |a_{n+1}| \leq |a_1| + |a_2| + \dots + |a_n| + |a_{n+1}|.$$

Therefore,

$$\left| \sum_{k=1}^{n+1} a_k \right| \leq \sum_{k=1}^{n+1} |a_k|$$

and we conclude that

$$\left| \sum_{k=1}^n a_k \right| \leq \sum_{k=1}^n |a_k| \quad \odot$$

Question 4

Exercise 1.2.8

Question 5

Exercise 1.2.12

Question 6

Grade the following proof: Prove that $\sqrt{3}$ is irrational. Does a similar argument work to show $\sqrt{6}$ is irrational?

Proof: To prove that $\sqrt{3}$ is irrational, we can use a proof by contradiction. The idea is to assume that $\sqrt{3}$ is rational, and then derive a contradiction.

Assumption: $\sqrt{3}$ is rational.

If $\sqrt{3}$ is rational, it can be expressed as a fraction $\frac{a}{b}$ in its simplest form, where a and b are integers with no common factors other than 1 (i.e., they are coprime), and b is not equal to 0.

So, we have: $\sqrt{3} = \frac{a}{b}$

Squaring both sides of the equation: $3 = \frac{a^2}{b^2}$

Rearranging the equation: $a^2 = 3 \cdot b^2$

From this equation, we can see that a^2 is a multiple of 3, which implies that a must also be a multiple of 3. Let's represent a as $3k$ where k is an integer:

$$(3k)^2 = 3 \cdot b^2$$

$$9k^2 = 3 \cdot b^2$$

$$3k^2 = b^2$$

Now, b^2 is also a multiple of 3, which means b must be a multiple of 3. However, this contradicts our initial assumption that a and b have no common factors other than 1 (i.e., they are coprime). This contradiction arises from assuming that $\sqrt{3}$ is rational.

Hence, our initial assumption that $\sqrt{3}$ is rational must be false, which means that $\sqrt{3}$ is irrational. Now, to address whether a similar argument works for $\sqrt{6}$:

No, a similar argument does not work for $\sqrt{6}$. The proof for the irrationality of $\sqrt{3}$ relies on the fact that it leads to a contradiction with respect to the common factors of a and b . However, for $\sqrt{6}$, this argument does not apply directly because the factors of 6 are not the same as the factors of 3. In fact, $\sqrt{6}$ is not irrational; it is a rational number. It can be expressed as the fraction $\frac{2\sqrt{3}}{3}$, which is a ratio of two integers.
